

## Early Journal Content on JSTOR, Free to Anyone in the World

This article is one of nearly 500,000 scholarly works digitized and made freely available to everyone in the world by JSTOR.

Known as the Early Journal Content, this set of works include research articles, news, letters, and other writings published in more than 200 of the oldest leading academic journals. The works date from the mid-seventeenth to the early twentieth centuries.

We encourage people to read and share the Early Journal Content openly and to tell others that this resource exists. People may post this content online or redistribute in any way for non-commercial purposes.

Read more about Early Journal Content at <http://about.jstor.org/participate-jstor/individuals/early-journal-content>.

JSTOR is a digital library of academic journals, books, and primary source objects. JSTOR helps people discover, use, and build upon a wide range of content through a powerful research and teaching platform, and preserves this content for future generations. JSTOR is part of ITHAKA, a not-for-profit organization that also includes Ithaka S+R and Portico. For more information about JSTOR, please contact [support@jstor.org](mailto:support@jstor.org).

## ON THE VERTICAL RANGE OF BIRDS IN COLORADO.

BY FRANK M. DREW.

COLORADO, lying between  $37^{\circ}$  and  $41^{\circ}$  north latitude and  $102^{\circ}$  and  $107^{\circ}$  west longitude, is preëminently a mountain state. Of its 104,500 square miles fully one-half is mountainous, the average elevation of the State being 6000 feet, with extremes of 3500 and 14,500 feet. Rising slowly from the Missouri River, the treeless plains, having already reached an altitude of 3500 feet at the eastern border of the State, thence continue to rise more rapidly, but yet gradually, to nearly half way across the State. There, at an elevation of about 6000 feet, the outlying foothills throw up a dam stretching north and south the full length of the State. Up into these foothills surge the waves of bird migration in spring to about 8000 feet — the altitude of the Great Parks which stretch their huge treeless surfaces atop the hills. And down these hills comes the return tide of birds in fall, a few to linger near the base, but by far the greater part passing on and down to an altitude lower than any found within the State.

Despite its latitude, which causes very hot summers, the average temperature is below that of other States in corresponding parallels. At an elevation of about 7000 feet, an approximate average for the year gives a temperature of  $+47^{\circ}$  F.; for winter — December, January, February — of  $+26^{\circ}$ ; spring — March, April, May — of  $+47^{\circ}$ ; summer — June, July, August — of  $+69^{\circ}$ ; autumn — September, October, November, — of  $+46^{\circ}$ . Missouri, in nearly the same latitude, has an approximate mean annual temperature of  $+55^{\circ}$ .

The average temperature on the higher peaks, reaching up to from 12,000 to 14,000 feet, usually ranges from  $20^{\circ}$  to  $30^{\circ}$  lower than these figures, the difference being greatest in summer. Continued observations at several stations give an average of about  $+48^{\circ}$  for the mean annual temperature at 6000 feet, and of  $+38^{\circ}$  at 10,000 feet elevation. Timber-line, which varies from 11,000 feet to 12,000 feet, has an average annual temperature — according to Gaunet — of  $+30^{\circ}$ . Notwithstanding the heavy and long-continued snows of winter, and the frequent rains in summer,

the mean annual precipitation will not exceed 20 inches,—being 12 to 14 inches on the plains, and increasing to 32 inches in the mountains.

As is well known, the flora of the plains is strongly characterized by buffalo grass, sun flowers, and cacti, and as a natural result, Fringillidæ and Raptores predominate there over all other forms of bird life.

Entering the foothills, which reach an average elevation of 8000 feet, the piñon (*Pinus edulis*) and dwarf oak (*Quercus alba gunnisoni*) at once become abundant, and their matted clumps and tangled underbrush make hiding places for many Warblers. On the shoulders of the foothills rest the mountain parks, with a mean elevation of 8000 feet. They are treeless and plain-like, being covered with grass and sage, save where the grass has been killed out by grazing herds; then the shifting sands prevent aught but sage from maintaining a foothold.

The bases of the main peaks have an elevation of about 8000 feet; thence they rise rapidly, drawing themselves aloof from the life of the plains. And, indeed, it is only those birds which pass up into these uppermost levels which can properly be called mountain inhabitants, the great parks thus forming the real dividing ground between the summer camps of the hardier lowland birds and the homes of those to the manor born. Nor do the straggling migrants but rarely wander over the mountains themselves, but, instead, into these parks.

The latitudinal range of birds in the United States has been quite fully worked out, and notes on the close connection between vertical and geographical distribution are not few; yet, so far as I know, no one has tabulated the vertical range. References to elevations at which birds have been found in summer are quite frequent. Especially is this the case in Allen's 'Ornithological Reconnaissance in Kansas,' etc., and Ridgway's 'Ornithology of the 40th Parallel,' and many are given by Mr. T. M. Trippe in Coues's 'Birds of the Northwest.' I have freely borrowed from these sources, as well as from Henshaw's 'Report' on birds in volume V of Wheeler's Surveys, and from Ridgway's paper on Colorado Birds in 'Bull. Essex Inst.', Vol. V, No. 11.

One working in different parts of the State will soon perceive the floral limits to be quite sharply defined. To a certain, though less extent, the birds also are shut in by almost intangible barriers.

But so evident is it that food supply is the main factor in bird distribution—this regulated by vegetation, and this in turn by climatic influences—that it only needs be said that where food is, there the birds will be found: as, *e. g.*, Creepers and Woodpeckers at 11,000 feet in winter, and Ouzels at the same season feeding in the icy torrents as high as 9000 feet.

Most birds range high up in summer and lower in fall; some have a range the reverse of this; while others early reach their nesting-sites and remain until the time for the complete semi-annual migration comes round.

Mr. T. M. Trippe, in 'Birds of the North-West,' p. 228, has noted the over-migration in spring of *Oreoscoptes montanus*. This trait is common to many, if not all, birds in vertical migration, though I believe not in latitudinal movements. Another peculiarity of vertical migration is the upward range of many birds during the Indian summer days of autumn, *e. g.*, *Sturnella neglecta*, *Scolecophagus cyanocephalus*, *Gymnocitta cyanocephala*. This I believe to be the result of a scarcity of food at lower levels, though a somewhat similar reverse migration has been noted at the same season on the New England coast. (See B. N. O. C., Oct., 1880, p. 237, and Coues, B. N. W., p. 521.)

The following list, containing the results of five years' work in the State, is believed to be a complete one of the birds found within the boundaries of Colorado. To the south, in New Mexico, climate, and to the north lower average elevation of the mountains, causes considerable variation in the vertical range of birds. But in Colorado, I think, this range is nearly uniform, there being but few birds of the list not of general distribution in the State, and these are chiefly found in the southern portion. Mountain ridges *en échelon* combine to catch many a straggling bird. Several such are entered on but a single record, and while showing nothing of distribution, yet may be of interest in future work. Some of those accredited on scanty data are followed by the name of the authority. In the parks are found the only apologies for lakes which the State affords, and around them the few Water Birds which remain during the summer cluster to breed. In many of the upper valleys beaver streams often provide suitable homes for isolated pairs of Ducks, but by far the greater number of our Water Birds are migrants.

No claim of completeness is made, the notes being offered as a basis on which to engraft other observations, and which,

with further notes on temperature and the flora, may eventually serve to show to what extent there is a correspondence between vertical and latitudinal distribution. As most of the birds noted are summer visitants, the column showing winter range is mostly blank. The upper nesting limit is usually easily determined; the lower not so readily, as many species, in suitable localities, nest down to sea-level. But in some cases, as in *Lagopus leucurus*, *Regulus calendula*, and some others, quite well-defined limits exist, above or below which few, if any, of these birds are found during the nesting season.

*Lophortyx californianus*, *Ortyx virginianus*, and perhaps some others, have been introduced in the vicinity of Denver, but probably as yet their range does not extend above 5000 feet.

The figures in the columns under the headings, 'Spring,' 'Summer,' etc., refer to elevations in feet above sea-level. The 'Breeding Range' will give the full summer distribution of those remaining through that season. In the records of spring and fall migrants I have aimed to show how *high* the birds wander, and so have merely noted the upper limit of the range of birds which are generally distributed below the altitude given. But in the case of birds of erratic or little-known distribution, both the upper and lower levels inclosing their range are given. A ? following the figures in a few cases means probability amounting almost to certainty. The 'Plains' include a large part of adjoining Kansas.

The nomenclature is that of Ridgway's 'Catalogue of the Birds of North America.' But if sub-species '*montana*' is merely a modified form of *Certhia familiaris rufa*, why not put it so, and let it be understood that the last-named form is merely a modification of the preceding, as is now so well accepted in the case of varieties of the first remove? The same applies to *Pipilo maculatus arcticus megalonyx*.
